(57) **ABSTRACT**

A game engine is configured to accept human intelligence tasks as in-game content and present the in-game content to the game player. A method performed by the game engine enables performance of human intelligence tasks, such as visual discrimination, in a video game context. The game engine may receive a definition of human intelligence tasks from one or more remote sources. The game engine may present the human intelligence tasks to multiple video game participants as in-game content. The game engine defines and enables game play rules for the in-game content. The game play rules set parameters for the multiple video game participants to perform the human intelligence tasks to achieve desired results. The game engine may award each of the multiple video game participants an improved game score upon successful performance of the human intelligence tasks in accordance with the game play rules. The game engine may measure success by consistency in responses between different participants or trials.

# ENTERTAINMENT SYSTEM FOR PERFORMING HUMAN INTELLIGENCE TASKS

## CROSS-REFERENCE TO RELATED APPLICATION

This application claims priority to and is a continuation of U.S. patent application Ser. No. 15/948,924, filed on Apr. 9, 2018, issued as U.S. Pat. No. 10,449,442, which claims priority to and is a continuation of U.S. patent application Ser. No. 15/443,984, filed on Feb. 27, 2017, now issued as U.S. Pat. No. 9,937,419, which claims priority to and is a continuation of U.S. patent application Ser. No. 13/532,675, filed on Jun. 25, 2012, now issued as U.S. Pat. No. 9,579,575, which claims priority to and is a continuation of U.S. patent application Ser. No. 12/362,396, filed on Jan. 29, 2009, now issued as U.S. Pat. No. 8,206,222, which claims priority pursuant to 35 U.S.C. § 119(e) to U.S. provisional application Ser. No. 61/024,347, filed Jan. 29, 2008, which applications are specifically incorporated herein, in their entirety, by reference.

## BACKGROUND

### 1. Field

The present disclosure relates to a gaming system that distributes tasks for performance by human intelligence and collects task results.

### 2. Description of Related Art

Various processing tasks exist that are difficult to perform using an automated algorithm, but that are relatively trivial for a human operator. For example, there is a substantial need for identification, characterization, or classification of features of photographs, sounds and other digital data used to produce visual or auditory Image output. This identification, characterization or classification either eludes computerized systems or requires human confirmation of computerized analysis. At least one computerized system exists to distribute such tasks to human operators in exchange for remuneration of some kind. For example, Amazon developed a system coined Mechanical Turk (<http://www.mturk.com/mturk/welcome>) that pays humans to perform Human Intelligence Tasks. Mechanical Turk defines Human Intelligence Tasks as “simple tasks that people do better than computers.” As an example, a person may be able to perform the task of identifying whether a specific type of object (for example, a pizza parlor) appears in a photograph or video sequence easier and more efficiently than a computer.

This model, paying for people to perform tasks, fails where the cost of the labor to perform a task exceeds the value of the tasks. For example, a task may be to identify parking meters in a system similar to Google Earth™. The value to the company seeking the information may be only a tenth of a penny per parking meter. A human operator may perform the task a maximum of 250 times in an hour, on average. Performed by a person, this task may not make financial sense, even when pricing labor in cheap offshore outsourced labor markets.

Complicating this problem, humans often make errors even in those tasks that they are uniquely best suited to perform. Many errors arise through carelessness or just normal momentary lapses in concentration. Some people may intentionally enter incorrect data, either maliciously, or

2

in order to boost their pay rate by creating false results. Accordingly, there is a need for a system that effectively distributes tasks and collects results for human intelligence tasks, for example visual identification tasks, in a more cost-effective manner and in a manner that prevents or corrects erroneous entries.

Various distributed computing systems are known, in which a server distributes processing jobs to a plurality of clients for performance by the client during processor idle time, and collects results. However, the processing tasks in those prior art systems are performed solely by the client processor in cooperation with a server, and do not involve or require human intelligence input. In addition, various methods and systems are known for distributing updated digital image or audio data to be output by a game engine during game play at one or more local clients, for advertising or game enhancement purposes. Some such prior systems also collect use information regarding user interaction with the updated data, e.g., number of views or clicks, and report the use information to a central server for analysis or control of distributed updates. However, such systems do not attempt to solve any defined problem through human interaction via game play. Problem solution through game play requires unique methods and solutions that have not been contemplated in any prior art system. Indeed, it has not been contemplated that game play can be used to solve problems requiring human intelligence input, especially problems involving the identification, characterization or classification of visual images or audible output based on qualities that humans are uniquely adapted to recognize, but that are difficult or impossible to recognize using an automated algorithm.

## SUMMARY

There are numerous video and other games where players navigate rich visual, audio or other environments. These games may involve single player scenarios with many players using the same environment, but in instances that do not include other players. Multiplayer and massively multiplayer virtual environments also exist. In general, systems for distributing updated data, including digital data for visual images or audible sounds output during game play, may be adapted for the solution of problems benefiting from human intelligence input.

Before proceeding to solve such problems, they must be defined prior to system input, and broken down to a solution process. The solution process presents digital data as visual or audible output for human interaction in the context of game play, and analyzes game play input to infer the presence or absence (or probability of presence or absence) of some defined quality in discrete pieces of the digital image data. The discrete pieces of data may be perceivable in system output as still images, video clips, sound clips, or some combination of the foregoing. In general the digital image data may be derived from real-world imagery, for example, photographs, video clips, sound recordings, x-ray images, magnetic resonance images, ultrasound images, or any imagery of persons or objects or objects existing in the real world. Such imagery is generally more likely to include human-recognizable qualities that cannot readily be discerned by automated analysis, as compared to computer-generated data that may be more readily characterized by machines than by humans. The problem definition involves determining the digital image data to be processed, the quality or qualities to be determined by human intelligence input during distributed game play, and the desired outputs.

A problem definition unit may comprise a server operating a user interface and application that presents possible problem parameters and receives input indicating a selection of parameters defining the problem to be solved. A few examples, of such problem parameters are presented in the instant disclosure, which should not be regarded as limiting to the scope of what is claimed.

Once the problem parameters have been defined, a solution generation and administration system may define and operate a solution system designed to operate over a distributed hardware network. Generally the hardware network includes at least one server for distributing the digital image data to a plurality of client devices and client devices at which human intelligence input is received in response to visible or audible output at the client device, during game play. The components of the network are in communication using any suitable network, including but not limited to the Internet, a local area network, cellular telephone network, satellite, cable, or optical fiber network, or some combination of the foregoing. The solution system operating on this hardware network may include server and client application modules designed to receive and distribute the digital image data, receive human intelligence input during game play, provide the input for automated analysis to infer problem solution data, and report solution status and results. Solution systems may be generated manually by a solution engineer, may be automatically generated to work with constrained problem parameters within a defined hardware and software system, or some combination of manual and automatic generation.

The solution system should be designed to address a unique aspect of problems depending on human intelligence input, and particularly on problems depending on identification, characterization, or classification of sensible output according to human-recognizable terms. Namely, the unique aspect that a correct solution depends on correct human intelligence input. At the same time, correctness or reliability of a solution cannot readily be assessed without confirming human intelligence input. If it were otherwise, there would be no need for human intelligence input to solve the particular problem. In addition, problem solving by humans inherently involves a high error rate, either intentional or unintentional. Therefore, a robust solution system should include a confirmation procedure for the human intelligence input, such as, for example, presenting identical digital image data at different times on the same client, and/or at different clients, and assessing consistency between the response inputs received. In general, a high degree of consistency between responses may be used to indicate a correct result, while a high degree of inconsistency correlated to an incorrect or indeterminate result, which may call for further solution or a conclusion that a particular result is indeterminate or uncertain. For example, in some cases it may not be clear just what a particular image represents. Furthermore, identifying a particular image as being indeterminate may make submission of those indeterminate images to prior art systems (such as Mechanical Turk) cost-effective, as the value of a complete, fully determinate set of images may be higher than the cost of identifying the several remaining indeterminate images after applications of the inventions disclosed herein.

Another unique aspect of the problems addressed by the present disclosure is that the human intelligence task to be performed on each piece of human task data may be of such low economic value that a payment-for-services model is not economically feasible. In the alternative, it may be simply desired to save cash requirements or other costs

associated with such a model. Furthermore, certain tasks are performed by human brains differently when done in a competitive environment, when done for pleasure, when done in a setting or manner that triggers the fight-or-flight response, or when done for reasons other than remuneration. For example, people may be more likely to trust their instinctive guess as to the fastest path between two points when in a competitive environment where time spent calculating the faster path would reduce the likelihood of victory. It is therefore desirable to solicit and receive the human intelligence input from multiple persons, such as from a massive group of participants, without paying for the input and while still providing the participants with an incentive to participate and to provide correct input. It is known that large groups of participants will willingly participate in online gaming for the entertainment value afforded by the game, the satisfaction of besting others or ones own past achievements by more adroitly performing game requirements, or other intangible benefits. The game system may therefore harness the motivations present in game play to motivate participation in evaluating the human task data, and reward input indicating human intelligence input within the context of the game's reward or scoring system. It should be understood that games or either virtual environments that simulate other people, or even single player games or virtual environments, can also serve as a source of human intelligence input.

Using at least one piece of data for which human identification or other processing is required ("human task data"), a solution system may inject one or more pieces of human task data into a computer game in a manner that includes task data output in play according to the goals of the game. Human task data may include digital image data or other data capable of producing sensible output for which human identification, characterization, or classification is desired. The game may be designed such that user input interacting with image or auditory output appearing in the game provides information about a classification into which a particular piece of human task data falls, or an identification or characterization that pertains to the particular piece of human task data.

For example, it may be desirable to identify the breed of dogs appearing in photographs found on the internet. A programmer may write software that identifies potential dog images, which may be operated to collect such images from an available database. Alternatively, photographs found on pages with text about dogs, or photographs bearing a file name indicating a dog may be gathered. These images (or the portions thereof that are most likely to be dogs) may be loaded into a walk-through "first person shooter" game. The walkthrough may be performed dynamically or not dynamically. Players may be told that shooting a dog of a specified breed will result in extra points, a higher score, in-game currency, extra ammunition or other in-game rewards within the game context.

Rewards may be given immediately for shooting any human task data, or the rewards may be delayed until after processing of player behavior data takes place. The behavior of players to the injected human task data may then be recorded, optionally transmitted to a centralized data processing facility, and analyzed. If a set number of players "shoot" the dog in image 205 when instructed to shoot a pit bull or a fixed ratio of players do so, the photograph is identified as a pit bull. This assumes also that certain players misidentify the photograph. Accordingly, it may be desirable to use a percentage, such as 80%, for example. The photograph may then be rotated out and/or the players who have

5

“shot” the dog correctly may be given their reward. Thus, scores and rewards may be awarded after the system has measured consistency between a number of user responses to infer a result that a particular image is indeed a pit bull. This analysis may be performed during game play so that the points can be awarded during game play or no later than at the completion of the game when final results are tallied. Other rewards may be awarded prior to analysis. For example, the game may immediately award one point for “shooting” any image presented, and later award five points if the image shot is the same as shot by a majority or super-majority of the participants. An additional incentive can be provided to the first player to correctly identify an image, such as by later awarding reputation points unrelated to the game (such as Microsoft’s Xbox Live Gamer Score points). Such an additional incentive could be utilized to offset the disincentive that may be created when an image or task is correctly performed but the system lacks sufficient data to verify the player input and award points based thereon. Another implementation may permit users to undo an incorrect identification (for example, as by clicking an “oops” button after shooting an image of a squirrel when they are tasked with shooting a dog), and may optionally adjust the data utilized by the system and/or the user’s score to reflect this correction.

A particularly vexing problem for mathematicians and planners is the “travelling salesman’s problem”, one of a class of problems known as “NP-complete problems”. In one classic example of the problem, a salesman is required to visit N locations in the most time or distance-efficient manner. However, finding the shortest route connecting N points, while solvable by testing every possible combination, is so computationally intensive that it is generally considered to be unsolvable for large numbers of points using existing computing resources. This problem is particularly well suited to the inventions at issue. Human beings spend hundreds of millions of hours annually navigating virtual 3-D environments within computer games. By adapting the map for which the shortest route is sought to a computer game, players would be presented with a digital model of the locations to be visited. The game is structured to require the players to travel between the points, and the relative efficiency of the various routing combinations tried by the players is tracked by the software. Real world factors, such as traffic flow, stop signs, one way streets, speed limits, and other things that impact transit speed can be accounted for by altering the routes within the game (as by lengthening game routes that correspond to lower speed limit real-world streets) and/or by altering the physics used by the game engine or altering the game map in ways that would not be possible within the real world. One such implementation might be to stretch the area of the game map corresponding to the city center (where real world speed limits are low) by different amounts depending on the time of day, with or without expanding surrounding areas of the map (as it is not necessary for game maps to follow laws of physics, allowing for example, a 5 square mile area to contain 10 square miles of territory). Points can be awarded to players for efficiently navigating the route. Alternatively, speed of navigation may simply be incorporated within the game as necessary or useful to a good game score or outcome.

A more complete understanding of the entertainment system for distributing and processing human intelligence tasks will be afforded to those skilled in the art, as well as a realization of additional advantages and objects thereof, by a consideration of the following detailed description. Ref-

6

erence will be made to the appended sheets of drawings which will first be described briefly.

## BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a flow chart showing exemplary steps of a method for obtaining and processing human intelligence input that may be performed by an entertainment system for solving problems using human intelligence input.

FIG. 2 is a system diagram showing exemplary components of an entertainment system for solving problems using human intelligence input.

## DETAILED DESCRIPTION

FIG. 1 is a flow diagram showing exemplary steps of a method 100 of performance of human intelligence tasks in a video game context, as may be performed by an entertainment system for solving problems using human intelligence input. An exemplary system is described later in the specification. At 110, the system may receive human intelligence tasks from multiple remote sources. The human intelligence tasks may comprise identifying photographs or parts of photographs, identifying sounds, or identifying or otherwise indicating any type of audio, video, routing or other type of data. The multiple remote sources may be businesses, online resources, or any other source that requires human intelligence to perform tasks.

At 120, the system may present the human intelligence tasks to multiple video game participants as in-game content. The in-game content may be quasi-content, meaning that the video game programmers did not specifically include the content as part of the video game. Rather, the human intelligence tasks may be adapted to fit the video game using real-life images, sounds or other data, and may be updated at various times after a game is coded and released. Various methods and systems for providing image, video and audio data after game release and including it in output during game play are known in the art, and any suitable method or system may be used. However, such prior art systems should be adapted such that the video, image or audio data is presented in a game context that solicits user input indicative of human intelligence input regarding the video, image, or audio output from the data.

At 130, the system may enable game play rules for the in-game content. The game play rules set the parameters for the multiple video game participants to perform the human intelligence tasks to achieve desired results within the context of game play. The game play rules may, for example, instruct the multiple video game participants in a “first-person shooter” video game to shoot only dogs of a specific breed. Once any given video game participant has achieved the desired results in accordance with the game play rules, the video game participant may receive a reward. At 140, the system may notify the multiple video game participants of the game play rules. At this point, the multiple video game participants may choose to participate in the in-game content for in-game or real-world rewards.

At 150, the system may reward the multiple video game participants upon successful performance of the human intelligence tasks in accordance with the game play rules. Successful performance may be measured by a measured degree of consistency of any action or set of actions within the video game by a given video game participant, as compared to actions by other participants responsive to the same data, or to prior actions by the same participant. The rewards may include in-game benefits, scores, prizes or a

form of currency used within the video game, or may involve real-world benefits, prizes or currency.

FIG. 2 is a block diagram illustrating an exemplary system **200** in accordance with the present disclosure. The system **200** may comprise a network host computer **204**, a plurality of clients **206**, a database server **208** and a database **210** all in communication via a Wide Area Network (WAN) **202**. The WAN **202** may enable communication between the network host computer **204**, the plurality of clients **206**, the database server **208** and the database **210**, and any suitable communication network, or combination of networks, may be used. The network host computer **204** may comprise a content management application **212**, which may be encoded on computer-readable media and configured for performing various actions as illustrated in the flowchart of FIG. 1. In the alternative, or in addition, each of the plurality of clients **206** may comprise a content management program **214**, which may also be encoded on computer-readable media and configured for performing various actions illustrated in the flowchart of FIG. 1. Some of the actions illustrated in the flowchart of FIG. 1 may be performed by the content management application **212**, while others may be performed by the content management program **214**. The database server **208** and attached database **210** may be coupled to the network host computer **204** to store the database used in the method illustrated in the flowchart of FIG. 1. Alternatively, the database server **208** and/or database **210** may be connected to the WAN **202** and may be operable to be accessed by the network host computer **204** via the WAN **202**.

The plurality of clients **206** may further comprise an internal hard disk or other storage device **216** for storing the game engine **214**, a processor **218** for executing the game engine **214** and/or performing other background tasks and an internal bus **220** for internally connecting the storage device **216** and the processor **218**. The storage device **216** may also be configured to store the database used method **100**. The outputs of the method illustrated by the flowchart of FIG. 1, the notification of violation of the guest requirements and termination of guest access, may be displayed on the clients **206** via a display **222**.

In accordance with the foregoing, system **200** comprises a server **204** configured for distributing digital image data to a game client **206** via a computer network **202**. The digital image data may represent visible or audible images of physical objects to be output during game play at the client.

The game client **206** is in communication with the server, and comprises a memory **216** holding the game engine **214**. The game engine may be configured to operate on the game client **216** output the digital image data as part of game output in response to receiving the digital image data from the server. The game client may receive and store the digital image data during game play, or prior to game play. The game engine may further be configured to contemporaneously output a game environment in coordination with and exclusive of the digital image data. That is, the game environment includes output data that is distinct from the digital image data, for example, background images, icons, sprites, avatars, menu screens, score and status data, and other data as known in the computer gaming arts. Also, the game environment operates in coordination with the digital image data, such that visible or audible output generated from the digital image data is output by the game client as an integrated part of game play.

The game engine **214** is further configured to modify a game reward status indicator, for example, a game score, responsive to user input received by the game client from a

user interface device **224** during game play. Examples of user interface devices include keyboards, touch screens, pointers, game controllers, microphones and pointing devices. The game engine is configured such that the modification to the game reward status correlates to a degree of consistency in human discrimination between images or audio clips included in the digital image data, as may be inferred from the user input. For example, more score points may be awarded for input consistent with that received from other clients for the same data, then for inconsistent input. Conversely, points may be deducted for inconsistent input. The game engine may be further configured to output a record identifying a sequence of the images output during game play correlated to the user input, the record sufficient for inferring a predetermined attribute of ones of the images.

The game client is may be further configured to transmit the record for inferring a predetermined attribute to the server. The server may be configured to receive individual game records from the different game clients. The server may compare such records during game play to assess consistency between responsive inputs received at different game clients. The server may then report on the measured consistency to the game clients, each of which may use the consistency data reported by the server to generate a game score or other game reward status indicator, prior to completion of the game. In the alternative, the server may compute a score or other game reward status indicator and report the computer status indicators or scores to the participating game clients.

In addition, the server may be configured to process the record using an inference algorithm to infer a probability that a predetermined attribute applies to the ones of the images. The predetermined attribute may be an identity of a person or object appearing in the particular images of the digital image data. For example, the attribute may comprise the name of a person, species of animal, or object name (e.g., "fire hydrant"). The predetermined attribute may be a characteristic of a person or object appearing in the particular images of the digital image data. For example, the attribute may comprise an emotional state indicated by a person's face or body language, for example, happy or sad, or a location where a photograph was taken, e.g., "London" or "Paris". The predetermined attribute may be a classification of a person or object appearing in the particular images of the digital image data. For example, the attribute may comprise a label for various human or other classifications, for example, elderly, child, young, sexy, ugly, beautiful, fat, thin, and so forth. The server may assess a probability that a particular attribute applies to a particular image, video clip, or audio clip based on a number and/or percentage of consistent responses. For example, if 90% of responses indicate that a particular image is of a "beautiful woman," the server may infer that there is a high probability that the image indeed shows a beautiful woman. Conversely, for example, if only 30% of the responses agree that the image is of a "beautiful woman," the inferred probability assigned by the server may be quite low.

In the alternative, or in addition, the game client may be configured to process the record using an inference algorithm to infer a probability that a predetermined attribute applies to the ones of the images. This may be appropriate, for example, when a particular client has multiple users or when it is difficult to maintain reliable communications with the host server **204**.

System **200** may further include an image processor **226** coupled to the server. The image processor **226** may be configured for generating digital image data from photo-

graphic images or other real-world recorded data **228**. The image processor may obtain the data **228** from any available database, including database **208**. Input image data may also be obtained by searching any available records, for example using an Internet search engine to identify candidate images of a particular person, object, place, or the like. The image processor may convert data **228** to a format suitable for output by game engine **214** during game play.

As part of developing a solution system to a particular problem, the server **204** may be configured to define one or more attributes that are to be determined for images in the digital image data. These attributes may be of a type as previously discussed, and are to be determined in response to user input received by the game clients **206** during via user input devices **224**. Another part of solution system development includes generating task definition information. For example, a task definition may include an identification of eligible input images and an attribute label to the attribute to be determined from human intelligence input, for example, "toddler." The task definition may include one of more attributes to be determined. In addition, the task definition may specify other task criteria, for example a minimum number of participants and views per image, a task completion date, eligible game version or application for gathering human intelligence input, and so forth. The server **204** may be configured to distribute the task definition information to the game client **206**. The game engine may be configured to output a description of the one or more attributes provided by the task definition during game play. For example, the game engine may output a message instructing players to take specific actions with respect to images having specific attributes, to earn bonus points or other rewards. In general, the game engine is responsive to the task definition to receive and process the digital image data as output for game play.

The server **204** may be configured to divide the digital image data into distinct sets, and to distribute different ones of the distinct sets to different client machines. In other words, each client may receive a different part of the digital image data. These different parts may be overlapping. In the alternative, each client may receive the same digital image data. The server may distribute the digital image data in a single batch to the game client prior to commencement of game play. In the alternative, or in addition, the server may distribute the digital image data to the game clients meted out into a sequence of batches during game play. The digital image data may be pushed to the clients by the server, or pulled by the clients from the server.

The server **204** may distribute the digital image data via operation of a multiplayer game host operating on the server. The multiplayer host may operate in communication with the game engine on the game client to provide a multiuser online game in which multiple participants interact. In such embodiments, the user input indicating human intelligence response to particular task data may be provided directly to the server **204** by the participating game clients. The server may then perform all assessment tasks directed towards problem solution or scoring. In general, the computational and data processing operations necessary for operation of the solution system may be distributed between the client and server in any appropriate fashion.

Having thus described a preferred embodiment of and entertainment system for distributing and processing human intelligence tasks, and method of operating the system, it should be apparent to those skilled in the art that certain advantages of the within system have been achieved. It should also be appreciated that various modifications, adap-

tations, and alternative embodiments thereof may be made without departing from the scope and spirit of the present technology. The following claims define the scope of what is claimed.

What is claimed is:

1. A system comprising:

a server;

one or more processors;

a memory operably coupled to the server, the memory holding instructions that when executed by the one or more processors, cause the system to:

receive, on a first computer, a request for confirmation that a user of a second computer is a human;

automatically generate a computer game that presents two or more still images of real world imagery and requests that a user of the second computer identify an object that appears in at least one of the still images;

transmitting, to the second computer, at least a portion of the game;

receiving, at the first computer, the user's identification of the object;

comparing the user's identification with a database comprising information about which of the two or more still images contain which objects;

verifying whether the user's identification of the object received at the first computer match the database; and transmitting the result of the verification; and

where the system causes one or both of (a) a number of incorrect and correct identifications to be recorded within the database; and (b) the database to be queried at a later time to determine whether the user has correctly identified the object.

2. The system of claim 1, where the database is generated at least in part by gathering data generated by human users of the system.

3. The system of claim 1, where the real world imagery comprises photographs.

4. The system of claim 1, where the real world imagery comprises video clips.

5. The system of claim 1, where the real world imagery comprises computer-generated images.

6. The system of claim 1, where access to the system is denied based upon a failure of the user to generate a positive verification.

7. The system of claim 6, where notification of the failure of the user to generate the positive verification is transmitted to the second computer for display to the user.

8. A system comprising:

a server configured for distributing digital image data via a computer network;

the digital image data comprising visible or audible images of physical objects to be output to a client;

the server operably in communication with the client:

the server distributing to the client the digital image data containing a request to identify at least one object;

the server operably in communication with a database comprised of results of human analysis of the visible or audible images of at least some of the physical objects to be output to the client;

the server receiving a response from the client;

the server comparing the response from the client to at least one database entry;

the server verifying that the response matches the at least one database entry or the server verifying that the response does not match the at least one database entry; and

**11**

where the system causes the database to be queried at a later time to determine whether a human has correctly identified the at least one object.

9. The system of claim 8, where the digital image data is distributed prior to game play.

10. The system of claim 9, where a game environment includes output data that is distinct from the digital image data.

11. The system of claim 8, where the digital image data comprises sound clips.

12. The system of claim 8, where the digital image data comprises video clips.

13. The system of claim 8, where the digital image data comprises still images.

14. The system of claim 8, where: server denies access based at least in part on verification results.

15. The system of claim 8, where the server transmits verification results to a different computer.

16. A system comprising:  
a server configured for distributing digital image data via a computer network;  
the digital image data comprising visible or audible images of physical objects to be output to a plurality of clients;

**12**

the server operably in communication with the plurality of clients;

the server distributing the digital image data to the plurality of clients with a request that the clients identify at least one object in the digital image data;

the server comparing responses from the plurality of clients to determine whether the users of the clients substantially identify a same object;

recording the digital image data and the at least one object within a database; and

where the system causes one or both of (a) a number of incorrect and correct identifications to be recorded within the database; and (b) the database to be queried at a later time to determine whether a human has correctly identified the object in the digital image.

17. The system of claim 16, where the number of incorrect and correct identifications are recorded within the database.

18. The system of claim 16, where the distributing to the plurality of clients is substantially simultaneous.

19. The system of claim 16, where the database is queried at the later time to determine whether the human has correctly identified an object in the digital image data.

20. The system of claim 16, where the digital image data comprises a photograph.
